

TEMPERATURE

► So we have β measures the change in entropy of the system as energy is added

► When $\langle U \rangle$ is small, one unit of energy will rapidly increase entropy

► When $\langle U \rangle$ is large, one unit of energy will marginally increase entropy

$$\frac{dS}{d\langle U \rangle} = k_B \beta = \frac{1}{T}$$

► β Inversely correlates with the amount of average energy in the system

► We see that there is a duality, as β decreases, we can assume the density is flattening

▶ We can also interpret it as the particles are gaining more energy!

hence large β or low-temperature T

hence small β or high-temperature T

► From now on we will assume $k_b = 1$
